Matrix Multiplication Order in Combined Transformations

Bjoern Hartmann, CSE399 Fall 2002

23rd September 2002

Let $M_1, M_2, M_3, M_4$ be transformation matrices applied in sequence to a local frame, with $M_1$ applied first and $M_4$ applied last. Here is a quick overview of how to multiply the individual transformation matrices to obtain the combined matrix for four relevant cases:

1. Successive transformations of a local frame about the global, static reference frame:
   
   (a) Local $\rightarrow$ Global coordinate transformation:
   Premultiplication of regular transformation matrices, e.g.:
   $$P_{global} = M_4 \times M_3 \times M_2 \times M_1 \times P_{local}$$
   
   (b) Global $\rightarrow$ Local coordinate transformation:
   Postmultiplication of the inverse transformation matrices:
   $$P_{local} = M_1^{-1} \times M_2^{-1} \times M_3^{-1} \times M_4^{-1} \times P_{global}$$

2. Successive transformations of a local frame about the local, moving frame axes:
   
   (a) Local $\rightarrow$ Global coordinate transformation:
   Postmultiplication of regular transformation matrices:
   $$P_{global} = M_1 \times M_2 \times M_3 \times M_4 \times P_{local}$$
   
   (b) Global $\rightarrow$ Local coordinate transformation:
   Premultiplication of the inverse transformation matrices:
   $$P_{local} = M_4^{-1} \times M_3^{-1} \times M_2^{-1} \times M_1^{-1} \times P_{global}$$

Notes: “Regular transformation matrix” refers to a column-major matrix where the elemental rotation matrices around the $x$ and $z$ axes have the minus sign in the upper right corner. Cases 1(a) and 2(b) correspond to our intuitive understanding of fixed and local axis transformations, respectively, while the other case are simply derived by multiplying each side with the inverse of the compound transformation matrix.
